# Unconstrained Optimization Context

## Our Goal

Starting from an initial point  $\mathbf{x}_0$ , generate a sequence of iterates:

$$\{\mathbf{x}_k\}_{k=0}^{\infty}$$

such that  $f(\mathbf{x}_{k+1}) < f(\mathbf{x}_k)$  until convergence.

**Key Question:** How do we move from  $\mathbf{x}_k$  to  $\mathbf{x}_{k+1}$ ?

- Choose a direction  $\mathbf{p}_k$
- Choose a step length  $\alpha_k$
- Update:  $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k \mathbf{p}_k$

# Optimization on Level Sets

Level curves of  $f(\mathbf{x})$

6. Exercise

# Line Search Strategy

## Line Search Approach

1. Choose a search direction  $\mathbf{p}_k$
2. Find step length  $\alpha_k$  by approximately solving:

$$\min_{\alpha > 0} f(\mathbf{x}_k + \alpha \mathbf{p}_k)$$

3. Update:  $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k \mathbf{p}_k$

**Key insight:** Fix direction first, then find distance.

- Exact line search is expensive and unnecessary
- Use inexact line search with appropriate conditions
- Generate limited number of trial step lengths

# Trust Region Strategy

## Trust Region Approach

1. Build local quadratic model  $m_k(\mathbf{x}_k + \mathbf{p})$
2. Choose maximum distance  $\Delta_k$  (trust region radius)
3. Solve:  $\min_{\mathbf{p}} m_k(\mathbf{x}_k + \mathbf{p})$  subject to  $\|\mathbf{p}\| \leq \Delta_k$
4. If step is successful, accept; otherwise shrink  $\Delta_k$

**Key insight:** Fix maximum distance first, then find best direction.

Quadratic model:  $m_k(\mathbf{x}_k + \mathbf{p}) = f_k + \mathbf{p}^T \nabla f_k + \frac{1}{2} \mathbf{p}^T \mathbf{B}_k \mathbf{p}$

# Visualization of Trust region

## Trust Region Method

$$\text{Trust region subproblem: } \min_{\mathbf{p}} m_k(\mathbf{p}) = f_k + \mathbf{g}_k^T \mathbf{p} + \frac{1}{2} \mathbf{p}^T \mathbf{B}_k \mathbf{p}$$

$$\text{subject to } \|\mathbf{p}\| \leq \Delta_k$$

## Line Search vs Trust Region

Aspect	Line Search	Trust Region
Order of choice	Direction $\rightarrow$ Distance	Distance $\rightarrow$ Direction
Search direction	Fixed per iteration	Changes when $\Delta_k$ changes
Step acceptance	Always accept	May reject and retry
Computational cost	Lower per iteration	Higher per iteration
Robustness	Good for well-scaled problems	Better for ill-conditioned

## Steepest Descent Direction

### *Theorem (Steepest Descent Direction)*

*The direction of steepest decrease is the solution to:*

$$\min_{\mathbf{p}} \mathbf{p}^T \nabla f_k \quad \text{subject to} \quad \|\mathbf{p}\| = 1$$

**Solution:**  $\mathbf{p} = -\frac{\nabla f_k}{\|\nabla f_k\|}$

### Proof sketch.

Using  $\mathbf{p}^T \nabla f_k = \|\mathbf{p}\| \|\nabla f_k\| \cos \theta$ :

- Minimize  $\cos \theta$  subject to  $\|\mathbf{p}\| = 1$
- Minimum occurs when  $\cos \theta = -1$  (i.e.,  $\theta = \pi$ )
- This gives  $\mathbf{p} = -\nabla f_k / \|\nabla f_k\|$

## General Descent Directions

### Definition (Descent Direction)

A direction  $\mathbf{p}_k$  is a **descent direction** if:

$$\mathbf{p}_k^T \nabla f_k < 0$$

Equivalently, the angle  $\theta_k$  between  $\mathbf{p}_k$  and  $-\nabla f_k$  satisfies  $\theta_k < \pi/2$ .

### Why Descent Directions Work

From Taylor expansion:  $f(\mathbf{x}_k + \epsilon \mathbf{p}_k) = f(\mathbf{x}_k) + \epsilon \mathbf{p}_k^T \nabla f_k + O(\epsilon^2)$

If  $\mathbf{p}_k^T \nabla f_k < 0$ , then  $f(\mathbf{x}_k + \epsilon \mathbf{p}_k) < f(\mathbf{x}_k)$  for sufficiently small  $\epsilon > 0$ .

# The Step Length Tradeoff

## Fundamental Challenge

We want to choose  $\alpha_k$  to minimize  $\phi(\alpha) = f(\mathbf{x}_k + \alpha \mathbf{p}_k)$ , but:

- Exact minimization is too expensive
- Need substantial reduction in  $f$
- Cannot spend too much time choosing  $\alpha_k$

**Solution:** Use inexact line search with appropriate termination conditions

- **Sufficient decrease:** Ensure adequate reduction in  $f$
- **Curvature condition:** Prevent steps that are too short
- **Bracketing + interpolation:** Efficient implementation

## Sufficient Decrease Condition (Armijo)

### Definition (Armijo Condition)

$$f(\mathbf{x}_k + \alpha \mathbf{p}_k) \leq f(\mathbf{x}_k) + c_1 \alpha \nabla f_k^T \mathbf{p}_k$$

where  $c_1 \in (0, 1)$  (typically  $c_1 = 10^{-4}$ ).

- Ensures reduction proportional to step length and directional derivative
- Linear function  $l(\alpha) = f(\mathbf{x}_k) + c_1 \alpha \nabla f_k^T \mathbf{p}_k$
- Since  $c_1 < 1$ , line  $l(\alpha)$  lies above  $\phi(\alpha)$  for small  $\alpha$
- **Problem:** Satisfied by all sufficiently small  $\alpha$

## Curvature Condition

### Definition (Curvature Condition)

$$\nabla f(\mathbf{x}_k + \alpha_k \mathbf{p}_k)^T \mathbf{p}_k \geq c_2 \nabla f_k^T \mathbf{p}_k$$

where  $c_2 \in (c_1, 1)$ .

### Intuition:

- Left side is  $\phi'(\alpha_k)$ , right side is  $c_2 \phi'(0)$
- If slope  $\phi'(\alpha)$  is strongly negative  $\Rightarrow$  can reduce  $f$  more
- If slope is only slightly negative or positive  $\Rightarrow$  terminate

### Typical values:

- $c_2 = 0.9$  for Newton/quasi-Newton methods
- $c_2 = 0.1$  for conjugate gradient methods

## Wolfe and Strong Wolfe Conditions

### Wolfe Conditions

$$f(\mathbf{x}_k + \alpha_k \mathbf{p}_k) \leq f(\mathbf{x}_k) + c_1 \alpha_k \nabla f_k^T \mathbf{p}_k \quad (1)$$

$$\nabla f(\mathbf{x}_k + \alpha_k \mathbf{p}_k)^T \mathbf{p}_k \geq c_2 \nabla f_k^T \mathbf{p}_k \quad (2)$$

with  $0 < c_1 < c_2 < 1$ .

### Strong Wolfe Conditions

Replace second condition with:

$$|\nabla f(\mathbf{x}_k + \alpha_k \mathbf{p}_k)^T \mathbf{p}_k| \leq c_2 |\nabla f_k^T \mathbf{p}_k|$$

Forces  $\alpha_k$  to lie near stationary points of  $\phi(\alpha)$ .

# Wolfe Conditions Illustration

## Existence of Wolfe Step Lengths

### *Theorem (Existence Theorem)*

*Suppose  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  is continuously differentiable,  $\mathbf{p}_k$  is a descent direction, and  $f$  is bounded below along the ray  $\{\mathbf{x}_k + \alpha \mathbf{p}_k \mid \alpha > 0\}$ .*

*Then for  $0 < c_1 < c_2 < 1$ , there exist intervals of step lengths satisfying both the Wolfe conditions and the strong Wolfe conditions.*

### Key implications:

- Wolfe conditions are not too restrictive
- Always possible to find acceptable step lengths
- Line search algorithms are well-defined

  - Step-Length Conditions
  - The Wolfe Conditions
  - The Goldstein Conditions
  - Sufficient Decrease and Backtracking
4. Convergence of Line Search Methods
5. Rate of Convergence
6. Exercise

## Goldstein Conditions

### Definition (Goldstein Conditions)

$$f(\mathbf{x}_k) + (1 - c)\alpha_k \nabla f_k^T \mathbf{p}_k \leq f(\mathbf{x}_k + \alpha_k \mathbf{p}_k) \leq f(\mathbf{x}_k) + c\alpha_k \nabla f_k^T \mathbf{p}_k$$

with  $0 < c < \frac{1}{2}$ .

- **Right inequality:** Sufficient decrease (same as Armijo)
- **Left inequality:** Controls step length from below
- Both conditions use same parameter  $c$

### Comparison with Wolfe:

- (Yes) Simpler (one parameter vs two)
- (No) May exclude minimizers of  $\phi(\alpha)$
- (No) Not well-suited for quasi-Newton methods

## Backtracking Line Search Algorithm

---

### Algorithm Backtracking Line Search

---

**Require:** Choose  $\bar{\alpha} > 0$ ,  $\rho \in (0, 1)$ ,  $c \in (0, 1)$

- 1: Set  $\alpha \leftarrow \bar{\alpha}$
  - 2: **while**  $f(\mathbf{x}_k + \alpha \mathbf{p}_k) > f(\mathbf{x}_k) + c\alpha \nabla f_k^T \mathbf{p}_k$  **do**
  - 3:      $\alpha \leftarrow \rho \alpha$
  - 4: **end while**
  - 5: **return**  $\alpha_k = \alpha$
- 

**Parameters:**

- $\bar{\alpha} = 1$  for Newton/quasi-Newton methods
- $\rho \in [0.1, 0.8]$  (contraction factor)
- $c = 10^{-4}$  (sufficient decrease parameter)

**Termination:** Guaranteed in finite steps since  $\alpha$  becomes small enough.

# Properties of Backtracking

## Key Properties

- **Simplicity:** Only uses sufficient decrease condition
- **Efficiency:** Cheap function evaluations
- **Robustness:** Always finds acceptable step
- **Flexibility:** Can use safeguarded interpolation for  $\rho$

Why it works:

- Either accepts initial step  $\bar{\alpha}$
- Or finds step short enough for sufficient decrease
- But not too short: within factor  $\rho$  of rejected step

**Practical enhancement:** Use polynomial interpolation to choose  $\rho$  adaptively.

# Lipschitz Continuous Functions

## Definition (Lipschitz Continuity)

A function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  is **Lipschitz continuous** on a set  $S$  if there exists a constant  $L \geq 0$  such that:

$$\|f(\mathbf{x}) - f(\mathbf{y})\| \leq L \|\mathbf{x} - \mathbf{y}\|$$

for all  $\mathbf{x}, \mathbf{y} \in S$ .

The smallest such constant  $L$  is called the **Lipschitz constant**.

## Key Properties:

- Lipschitz  $\Rightarrow$  uniformly continuous
- Bounds the "steepness" of  $f$
- If  $f$  is differentiable:  $L = \sup \|\nabla f(\mathbf{x})\|$

## Zoutendijk's Theorem

### Theorem (Zoutendijk's Theorem)

Consider iterations  $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k \mathbf{p}_k$  where  $\mathbf{p}_k$  is a descent direction and  $\alpha_k$  satisfies the Wolfe conditions.

Suppose  $f$  is bounded below, continuously differentiable in a neighborhood of the level set  $\mathcal{L} = \{\mathbf{x} : f(\mathbf{x}) \leq f(\mathbf{x}_0)\}$ , and  $\nabla f$  is Lipschitz continuous on  $\mathcal{L}$ .

Then:

$$\sum_{k \geq 0} \cos^2 \theta_k \|\nabla f_k\|^2 < \infty$$

where  $\cos \theta_k = \frac{-\nabla f_k^T \mathbf{p}_k}{\|\nabla f_k\| \|\mathbf{p}_k\|}$ .

## Global Convergence Result

### Corollary (Global Convergence)

*If our method for choosing the search direction  $\mathbf{p}_k$  in the iteration ensures that the angle  $\theta_k$  between the negative gradient  $\nabla f_k$  and the search direction  $\mathbf{p}_k$  is bounded away from  $90^\circ$ , there exists a  $\delta > 0$  such that  $\cos \theta_k \geq \delta > 0$  for all  $k$ .*

*Then:*

$$\lim_{k \rightarrow \infty} \|\nabla f_k\| = 0$$

### Applications:

- **Steepest descent:**  $\cos \theta_k = 1$
- **Newton:** With proper modifications
- **Quasi-Newton:** With positive definite updates
- **Conjugate gradient:** With restarts

**Note:** "Global convergence" = convergence to stationary points, not global minima.

  - Step-Length Conditions
  - The Wolfe Conditions
  - The Goldstein Conditions
  - Sufficient Decrease and Backtracking
4. Convergence of Line Search Methods
5. Rate of Convergence
6. Exercise

## Rate of Convergence

### Convergence Rates Depend on Method

- **Steepest descent:** Linear convergence, can be very slow
- **Newton's method:** Quadratic convergence near solution
- **Quasi-Newton:** Superlinear convergence
- **Conjugate gradient:** Finite termination (quadratic functions)

### Key factors affecting rate:

- Condition number of the Hessian
- Choice of search direction
- Quality of line search
- Problem structure

**Reference:** Nocedal & Wright, Chapter 3, pages 47-51 for detailed analysis.

## Exercise

### Exercise: Line Search on Himmelblau Function

Consider the Himmelblau function:

$$f(x, y) = (x^2 + y - 11)^2 + (x + y^2 - 7)^2$$

We want to find minima using a line search method with the following steps:

1. Implement a backtracking line search algorithm to find a step length  $\alpha_k$  that satisfies the Wolfe conditions.
2. Use the steepest descent direction for the search direction  $\mathbf{p}_k$ .
3. Plot the convergence path on the level sets of  $f$ .
